How do I split and combine files in Windows? I need to split large files into several small sized files and then combine them after I transfer them to another box. I'm fine with doing this on the command line. 1 ReadDiscussView Discussion Improve Article Save Article Like Article Split command in Linux is used to split large files into smaller files. It splits the files into 1000 lines per file(by default) and even allows users to change the number of lines as per requirement.The names of the files are PREFIXxaa, PREFIXxab, PREFIXxac, and so on. By default the PREFIX of files name is x and the default size of each split file is 1000 lines per file and both the parameters can be changed with ease. It is generally used with log and archive files as they are very large and have a lot of lines. So in order to break them into small files for analysis split command is used.Syntax:split [options] name of file prefix for new filesWorking with Split Command1. Split file into short files. Assume a file name with name index.txt. Use below split command to break it into pieces.split index.txtIndex.txt file is split into two pieces with name 'xaa' and 'xab'. It will have 1000 lines in each file by default. The name of split commands is 'xaa' and 'xab' as we have not set any prefix value.2. Split file based on number of lines.split -l 4 index.txt split_fileIndex.txt file is split into short files based on the number of lines which we want using -l option as shown.3. Split command with verbose option. We can also run split command in verbose mode by using '-verbose'. It will give a diagnostic message each time a new split file is created.split index.txt -l 4 --verboseHere, we have created a file with name index.txt which will be split into short files and verbose will give us the details of what are the tasks performed.Note: Here -l 4 is not necessary to use. It is used just for understanding purposes.4. Split file size using '-b' option.split -b 16 index.txt indexHere, it will split the file index.txt into separate files called indexxaa, indexxab,with each file containing 16 bytes of data in it.5. Change in suffix length. By default, the suffix length is 2. We can also change it using '-a' option.split -l 4 -a 4 index.txtIn this it has suffix length 4 on the split files.Note: Here -l 4 is not necessary to use. It is used just for understanding purposes.6. Split files created with numeric suffix. In general, the output has a format of x** where ** are alphabets. We can change the split files suffix to numeric by using the '-d' option.split -l 4 -d index.txtNote: Here -l 4 is not necessary to use. It is used just for understanding purposes.7. Create n chunks output files. If we want to split a file into three chunk output files then use the '-n' option with the split command which limits the number of split output files. split -n 3 index.txtIt will create three chunks of split files.8. Split file with customize suffix. With this command, we can create split output files with customizing suffix. Assume, if we want to create split output files with index suffix, execute the following command.split -l 4 index.txt split_index Split output files with index suffix will be created.Note: Here -l 4 is not necessary to use. It is used just for understanding purposes.9. Avoid zero-sized split files. There are situations when we split a small file into a large number of chunk files and this may lead to zero size split output files. They do not add any value so to avoid it we use the option '-e'.split -l 4 -e index.txtBy using this no zero size split output files will be created.Note: Here -l 4 is not necessary to use. It is used just for understanding purposes.10. Split the file into two files of equal length. To split a file equally into two files, we use the '-n' option. By specifying '-n 2' the file is split equally into two files.split -n 2 index.txt I have a big file and need to split into two files. Suppose in the first file the 1000 lines should be selected and put into another file and delete those lines in the first file. I tried using split but it is creating multiple chunks. 2 Linux systems provide a very easy-to-use command for breaking files into pieces. This is something that you might need to do prior to uploading your files to some storage site that limits file sizes or emailing them as attachments. To split a file into pieces, you simply use the split command.\$ split bigfile By default, the split command uses a very simple naming scheme. The file chunks will be named xaa, xab, xac, etc., and, presumably, if you break up a file that is sufficiently large, you might even get chunks named xza and xzz.Unless you ask, the command runs without giving you any feedback. You can, however, use the --verbose option if you would like to see the file chunks as they are being created.\$ split --verbose bigfile creating file 'xaa' creating file 'xab' creating file 'xac' You can also contribute to the file naming by providing a prefix. For example, to name all the pieces of your original file bigfile.xaa, bigfile.xab and so on, you would add your prefix to the end of your split command like so:\$ split --verbose bigfile bigfile. creating file 'bigfile.aa' creating file 'bigfile.ab' creating file 'bigfile.ac' Note that a dot is added to the end of the prefix shown in the above command. Otherwise, the files would have names like bigfilexaa rather than bigfile.xaa.Note that the split command does not remove your original file, just creates the chunks. If you want to specify the size of the file chunks, you can add that to your command using the -b option. For example: \$ split -b100M bigfile File sizes can be specified in kilobytes, megabytes, gigabytes ... up to yottabytes! Just use the appropriate letter from K, M, G, T, P, E, Z and Y.If you want your file to be split based on the number of lines in each chunk rather than the number of bytes, you can use the -l (lines) option. In this example, each file will have 1,000 lines except, of course, for the last one which may have fewer lines. \$ split --verbose -l1000 logfile log. creating file 'log.aa' creating file 'log.ab' creating file 'log.ac' creating file 'log.ad' creating file 'log.ae' creating file 'log.af' creating file 'log.ag' creating file 'log.ah' creating file 'log.ai' creating file 'log.aj' If you need to reassemble your file from pieces on a remote site, you can do that fairly easily using a cat command like one of these:\$ cat x?? > original.file \$ cat log.?? > original.file Splitting and reassembling with the commands shown above should work for binary files as well as text files. In this example, we've split the zip binary into 50 kilobyte chunks, used cat to reassemble them and then compared the assembled and original files. The diff command verifies that the files are the same.\$ split --verbose -b50K zip zip. creating file 'zip.aa' creating file 'zip.ab' creating file 'zip.ac' creating file 'zip.ad' creating file 'zip.ae' \$ cat zip.a? > zip.new \$ diff zip zip.new \$
